Laughter = Medicine!

• Laughter’s most profound effects occur on the immune system.
• Laughter $\uparrow \gamma$-interferon, $\uparrow$ B-cells, $\uparrow$ T-cells and $\downarrow$ stress hormones
• The average child laughs 100s of x/day
• The average adult laughs 12 x/day
• We need to find these lost laughs—and use them to our advantage!

Ah Ha!

SEBB Newsletter 1997
Hand-washing

The right way to wash your hands:

Thoroughly wash with soap and warm running water — rubbing your hands together for at least 10 seconds.

Hand-washing is the single most effective thing you can do to reduce the spread of colds and other infectious disease.

It’s not necessary to use anti-bacterial soaps when washing up. Regular soap and water do the job just fine.

Also, using germicidal soaps too often may produce antibiotic-resistant bacteria.

Widespread Location of Lymphoid Tissues!
**Immunity**

**Innate/Inborn/Nonspecific**

1. **Immediate**, upon exposure to threatening agent

2. $1^0$ effectors phagocytic specialists: neutrophils & macrophages

3. "Eyes" are Toll-like receptors (TLRs) which recognize & bind with generic invader markers

4. Inflammation, interferon, natural killer cells, complement (plasma proteins)

---

**Adaptive/Acquired/Specific**

1. **Delayed**, selective targeting based on prior exposure

2. $1^0$ effectors lymphocytes: T- & B-lymphocytes

3. "Eyes" are T- and B-cell receptors which bind with specific antigens

4. Cell-mediated & Humoral (Ab mediated) immunity

---

Really, a false separation, as incredible overlap & synergism!
Macrophage

Neutrophil

Hypothalamus

EP, endogenous pyrogen

NSAIDs e.g. Aspirin

Lactoferrin binds Fe\(^{2+}\) ↓ Replication

NO, nitric oxide toxic to microbes

Prostaglandins → ↑ Set point

↑ Phagocytosis

↑ Enzymatic rxns, Q10?

↑ Bacterial replication by ↑ Fe\(^{2+}\) requirement

Bradykinin
Eosinophil & Neutrophil
Chemotactic Substances
Heparin
Histamine
Platelet Activating Factors
Protease
Serotonin
Toxic Leukotrienes/SRSA

up to $\frac{1}{2}$ million per cell!
**Inflammation Steps**

1. Break in skin → Bacteria enter & reproduce
2. Mast cells release histamine
3. Vessel wall becomes sticky → Neutrophils & monocytes attach → diapedesis → chemotaxis
4. Chemotaxins attract more Neutrophils & monocytes
5. Monocytes swell → Macrophages

Redness, Heat, Swelling, Pain!
Glucocorticoids throw blanket over entire inflammatory process!

1. Certainly warranted to quiet down immune system during extreme flare ups of arthritis, asthma, poison ivy, rash, but must consider:

2. Destroy lymphocytes in lymphoid tissues.

3. ↓ Antibody/Immunoglobulin (Ig) production.

4. Make susceptible to bacterial infections.
Interferon Mechanisms

1. Virus enters a cell
2. Virus replicates in invaded cell
3. Cell releases interferon
4. Interferon binds with receptors on uninvaded cells
5. Uninvaded cells produce inactive enzymes capable of breaking down viral messenger RNA and inhibiting protein synthesis
6. Virus enters cell that has been acted upon by interferon
7. Virus-blocking enzymes are activated
8. Virus is unable to multiply in newly invaded cells

Viruses coming! Don’t breathe on me, Paul!
Activated Complement

The Big MAC to ❤! Osmotic explosion!

L Sherwood 2012
**WBC Adverse Effects**

- Leukocytes
- Anti-cancer drugs
- Benzene
- Nuclear blast
- Radiation

↓ Body defense vs. μ organisms!

↓ Professional phagocytes esp:
- Neutrophils
- Macrophages

Savior Lymphoid tissues or bone marrow transplant?

*cf: Leukemia* ≡ uncontrolled WBC proliferation, yet inadequate defense → other cell lines displaced → overwhelming infections & bleeding...
Commander-in-Chief of the Immune System!!

HIV tips the balance!!
The vital union that activates a helper T cell takes place only when the T cell recognizes both a “self” marker (rectangle) and a “nonself” antigen (triangle) on a macrophage.
Clonal Selection

Population of unactivated B cells, each a member of a different B-cell clone that makes a specific receptor, which is displayed on the membrane surface as a BCR.

Binding of antigen and interaction with helper T cell stimulates the matching B cells to divide and expand the clone of selected cells.

Plasma cells

Rough ER

Antibodies

Most of the new B cells differentiate into plasma cells, which secrete antibodies.

Memory B cells

A few of the new B cells differentiate into memory B cells, which respond to a later encounter with the same antigen.

L Sherwood 2012; cf: G&H fig 34-2
Typical IgG Antibody Structure

How do antibodies work?

Identical, specific antigen-binding sites

Antigen

Antibody

KEY

V = variable region
C = constant region

Dendritic Cells: Specialized Antigen-Presenting Cells (APCs) Sentinels in Almost Every Tissue!
Protein messages trigger responses

The pivotal discovery of lymphokines, the proteins by which immune cells communicate with each other, ushered in a new era of medical research. Scientists now produce some of them in sufficient quantities for promising therapies against a host of immunologic diseases.

1. Engulfing an invading organism and coupling with a helper T cell, a macrophage secretes the lymphokine interleukin-1 (IL-1), which activates the helper T cell. IL-1 also stimulates the brain to raise the body’s temperature, causing fever, which enhances the activity of immune cells.

2. The activated helper T cell produces interleukin-2 (IL-2), which stimulates other helper and killer T cells to grow and divide. The helper T cell secretes a lymphokine called B-cell growth factor (BCGF), which causes B cells to multiply.

3. As the number of B cells increases, helper T cells produce another lymphokine, B-cell differentiation factor (BCDF), which instructs some of the B cells to stop replicating and start producing antibodies.

4. Helper T cells also produce a lymphokine called gamma interferon (IFNγ), which has multiple effects. Like IL-2, it helps activate killer T cells, enabling them to attack the invading organism. Like BCDF, it increases the ability of B cells to produce antibodies. It also affects macrophages, keeping them at the site of the infection and helping them digest the cells they have engulfed.

5. Gathering momentum with each exchange of signals between macrophages and T cells, a lymphokine cascade amplifies the immune response until the enemy is overwhelmed by sheer strength of numbers.
Figure 34-3  Time course of the antibody response in the circulating blood to a primary injection of antigen and to a secondary injection several weeks later.
